11 BENTHIC ECOLOGY

11.1 INTRODUCTION

Iarnród Éireann plans to develop the Rosslare Europort Offshore Renewable Energy (ORE) Hub project to service the emerging offshore wind industry and help support the government's offshore wind target. The Proposed Development is located adjacent to Rosslare Europort on the South-East coast of Ireland. More detailed information on the Proposed Development is provided in EIAR Chapter 6: Project Description of Volume II of the Environmental Impact Assessment Report (EIAR) and associated documents that accompany the planning application.

The aim of this report is to provide information on the benthic ecology receptors within the proposed Rosslare Europort ORE Hub area (i.e. Benthic Study Site), which comprises the Foreshore Licence Area, as shown in Figure 11-1. Additional information, for the wider environs adjacent to the study site which may fall within the Zone of Influence (Zoi) of the Proposed Development was also collated. This information has been used to inform the EIAR and planning application for the Proposed Development.

All data collected are provided as separate appendices to this report as detailed in Table 11-1 below.

11.2 METHODS

11.2.1 DESKTOP REVIEW OF AVAILABLE INFORMATION

A desktop review of the available information for the Proposed Development area was carried out to collate and assess the existing benthic baseline data available for the Proposed Development site as shown in Figure 11-1. Additional information for the wider environs, to include a radius, extending approximately 20km out from the Proposed Development area, was included. This radius was considered appropriate relative to the scale and scope of the Proposed Development.

The sources accessed and reviewed included the following:

- Integrated Mapping for the Sustainable Development of Ireland's Marine Resource (INFOMAR): Bathymetry, seabed and sediment data.
- European Marine Observation and Data Network (EMODnet): EUSeaMap Predictive broadscale habitat map.
- National Biodiversity Data Centre: Species and habitat data.
- Rosslare Europort ORE Hub site specific multibeam survey data.
- Rosslare Europort benthic survey data related to previous dredge campaigns.

11.2.2 SUBTIDAL ECOLOGY

To obtain a clear understanding of the subtidal benthic habitat within the Benthic Study Site, a subtidal grab sampling and dropdown video survey was conducted. Based on the bathymetric and backscatter information obtained from the multibeam echosounder survey completed in November 2023, a total of 40 grab sampling stations were selected throughout the study area. Sample stations targeted areas indicated as sediment from the multibeam survey and represented a comprehensive spread of sample stations throughout the study site. Dropdown video stations were surveyed throughout the study site across a range of depths and differing bottom types (sediment, cobble, rock).

11.2.2.1 SEDIMENT GRAB SAMPLING

A total of 40 stations were selected throughout the Benthic Study Site for grab sampling to inform macrofaunal, particle size and organic content analysis. The stations were selected to provide a suitable spatial spread across the entire site while avoiding obvious areas of hard substrate as identified by the multibeam data. All grab sampling was carried out between 13th and 15th of February 2024 and all sample analyses were completed by 30th of March 2024.

Four grab samples were collected from each station suitable for grab sampling using a 0.1 m² Day (for soft sediment habitats) and 0.1 m² mini Hamon (for coarse sediments) as appropriate. Three of the samples were analysed for macrofauna and one for particle size and total organic carbon.

The location of each station was recorded by dGPS and an environmental data log for each station prepared. The log included the following information:

- Location

- Date and time
- Depth of water
- Sampler type (Day or Mini-Hamon Grab)
- Penetration depth of grab to nearest cm (Day grab samples only)
- Sediment surface colour (Day grab samples only)
- Description of obvious features (fauna/algae etc.)
- Presence of layering and depth of layering if present (Day grab samples only)
- Evidence on anoxic conditions (Day grab samples only)
- Weather and sea state.

Field methodology

- Grab deployment and recovery rates were maintained at <1 m/sec and <0.5 m/sec for the last 5 metres.
- The winch wire was kept as vertical as possible to ensure a vertical lift.
- The thickness of material at the centre of the grab was recorded to the nearest centimetre.
- Surface colour of the sediment and any smell (hydrogen sulphide, oil residue etc.) was recorded.
- A description of the sediment to include recognisable fauna, surface features, algae, etc. was made.
- Both the sediment within the grab and the washed fraction retained on the sieve were photographed.
- Four grab samples per station were collected: three for faunal analysis and one for analysis of sediment physico-chemical parameters (Particle Size Analysis (PSA), organic carbon/LOI).
- All sediment samples were frozen (<-18°C) in appropriately sealed containers.
- The faunal grab samples were emptied into a container and the grab rinsed thoroughly to avoid loss of the sample. The sample was then transferred portion by portion onto a 1 mm sieve as a sediment water suspension.
- Fragile animals were picked by hand during sieving to minimise damage.
- Once washed through, all material retained on the sieve was placed in a bucket and fixed in buffered 4% w/v formaldehyde solution.

Laboratory methodology

Loss on Ignition (Organic Matter)

- The collected sediments were transferred to aluminium trays, homogenised by hand and dried in an oven at 100° C for 24 hours.

- A sample of dried sediment was placed in a mortar and pestle and ground down to a fine powder.
- 1 g of this ground sediment was weighed into a pre-weighed crucible and placed in a muffle furnace at 450°C for a period of 6 hours.
- The sediment samples were then allowed to cool in a desiccator for 1 hour before being weighed again.
- The organic content of the sample was determined by expressing the percentage weight of the sediment after ignition over the initial weight of the sediment.

Granulometry

- Approximately 100 g of dried sediment was weighed out and placed in a labelled 1 L glass beaker to which 100 ml of a 6% hydrogen peroxide solution was added and allowed to stand overnight in a fume hood.
- The beaker was then placed on a hot plate and heated gently. Small quantities of hydrogen peroxide were added to the beaker until there was no further reaction.
- The beaker was then emptied of sediment and rinsed into a 63 µm sieve. This was then washed with distilled water to remove any residual hydrogen peroxide. The sample retained on the sieve was then carefully washed back into the glass beaker up to a volume of approximately 250 ml of distilled water.
- 10 ml of sodium hexametaphosphate solution was added to the beaker and this solution was stirred for ten minutes and allowed to stand overnight.
- The beaker with the sediment and sodium hexametaphosphate solution was washed and rinsed into a 63 µm sieve. The retained sample was washed into a labelled aluminium tray and placed in an oven for drying at 100°C for 24 hours.
- The dried sediment was then passed through a Wentworth series of analytical sieves (>8,000 to 63 µm; single phi units). The weight of material retained in each sieve was weighed and recorded. The material passed through the 63 µm sieve was also weighed and the value added to the value measured in the previous point.
- The total silt/clay fraction was determined by subtracting all weighed fractions from the initial starting weight of sediment, as the less than 63 µm fraction was lost during the various washing stages.
- Reporting of sediment samples was as a range of particle sizes indicated below:

1	PSA % <63
2	PSA % 63<125
3	PSA % 125<250
4	PSA % 250<500
5	PSA % 500<1000

6	PSA % 1000<2000
7	PSA % 2000<4000
8	PSA % 4000<8000
9	PSA % ≥8000

Preservation and storage of faunal samples

- Upon return to the laboratory, samples were washed of formalin and preserved in 70% alcohol.
- Prior to sorting and identification, the alcohol was removed from the sample by rinsing through a 1 mm sieve. The sample retained on the sieve was then transferred, by backwashing, into a white sorting tray.
- All the fauna was extracted by hand, using forceps or pipette, with the aid of a low power microscope and placed into suitable labelled containers. Specimens were stored in 70-80% industrial methylated spirits/water preservative.
- The fauna belonging to the major taxonomic groups was identified and enumerated using binocular stereo and compound microscopes. Standard identification keys for each phylum were used.
- Identification of major taxonomic groups to species level was made. Other minor groups (e.g. Porifera, Nemertea, Nematoda, Echiurida) were identified to the lowest possible taxonomic level.
- Species were assigned a code (AphiaID) in accordance with the WoRMS (World Register of Marine Species¹).

Statistical methods

Sediment particle size data was inputted into GRADISTAT to derive Folk Classifications.

All univariate and multivariate analyses were performed using Primer v7. Biological data was averaged and square root transformed, per station, prior to all analyses. One replicate from station 7 contained no fauna (7a), the sample was blackened and showed signs of anoxia when the container was opened. This didn't appear to be due to preservation issues, but this replicate was removed from analysis as it was a significant outlier. Environmental data was normalised.

11.2.2.2 SUBTIDAL DROPDOWN VIDEO SURVEY

A High Definition drop down video camera, separate stills camera and associated lighting system integrated into a steel frame were utilised to obtain video and stills imagery of the seabed. The system was linked to a top-side monitor and spatial encoding system which provided real-time viewing, spatial encoding and recording of the video. The stills camera was set to capture an image every 25 seconds and the associated data was recorded onto the camera SD card. Depth and time of each deployment was recorded manually. The field of view of the camera was calibrated "in water" prior to mobilising.

¹ <http://www.marinespecies.org/index.php>

The length of the video transect varied at each station depending on the uniformity of the seabed, but ranged between 5.6 and 149 m in total length. Vessel speed during transect was less than 0.3 knots. Field notes were made during recording from the live feed. All spatially encoded video captured is provided in Appendix 4 and the associated stills images in Appendix 5. Video surveys were conducted on 18th and 19th of May 2024.

Following a review of the video quality and the determination of its suitability for interpretation, each video segment was viewed at slow speed and start/stop. All species identified were recorded in a MS Excel proforma and matched to the video code (Appendix 6). Each video segment was spatially encoded in the field, relative to the vessel position, allowing GIS shapefiles associated with each transect segment to be produced. Following the guidance of Parry (2019), biotopes were assigned to each segment analysed based on the depth, geomorphology and dominant characterising species recorded along the transect. Biotopes were assigned according to the Marine Habitat Classification for Britain and Ireland (Connor *et al*, 2004).

11.2.3 INTERTIDAL ECOLOGY

Intertidal habitats are present within the Benthic Study Site, extending from the small boat harbour west for approximately 800 m (Figure 11-2). An area of rock armour protects this area from the east. The area is utilised by small local fishing boats and a number of makeshift access gangways surround the perimeter of the area. A small slipway is present to the east of the harbour and a second slipway and pontoon are present in the mid-section of the harbour.

A walkover survey of the intertidal area was carried out on 10th of October 2023 (low water height 0.7 m). A resurvey was carried out on 27th of May 2024 (low water height 0.7 m) to check for seasonal species that may have been absent during the October survey. The results of both surveys were combined.

The walk over surveys were carried out one hour before to one hour after low water. A meandering route through the intertidal area was taken. The physical features of the habitat (dominant shore type and sub habitats) were recorded. All macroalgae present were then recorded as present/absent and an abundance score on a SACFOR (Super abundant, Abundant, Common, Frequent, Occasional, Rare) scale was assigned. All faunal species noted were also recorded on a SACFOR scale and biotopes assigned.

11.2.4 WATER SAMPLING

Surface water samples were collected at 15 stations throughout the survey area. Station location and depth were recorded. Simultaneous with water sampling, *in-situ* readings of water temperature, conductivity, salinity and dissolved oxygen saturation were collected using a CTD meter just off the bottom of the seabed. All samples were stored in cool boxes and transported to the laboratory for analysis on the day following collection (16th of February 2024).

11.2.5 BIOTOPE MAPPING

As all grab sample stations and video transect lines were fully spatially referenced, subtidal biotopes maps were prepared by plotting the corresponding biotopes as an overlay on the multibeam data. This provided a high degree of spatial accuracy for the assigned biotopes.

Figure 11-2. Small boat harbour

11.3 RESULTS

11.3.1 DESKTOP STUDY

Figure 11-3 shows the predominant habitat map for the Benthic Study Site and adjacent seabed. These data are derived from multibeam echosounder data and seabed sampling data acquired during the INFOMAR and INSS national seabed mapping programmes which form the primary sources of data used in the generation of this collated seabed classification. Areas where there is no multibeam data have been filled by EUSeaMap (predictive broadscale habitat map). The map indicates that the majority of the Benthic Study Site and adjacent seabed is comprised of shallow sublittoral sand and shallow sublittoral coarse sediment with pockets of shallow sublittoral rock and biogenic reef and shallow sublittoral mud. Shallow sublittoral sand and shallow sublittoral coarse sediment dominates the majority of the area surrounding the Benthic Study Site, while an area of shallow sublittoral mixed sediment is located to the north. It should be noted that the predictive habitat mapping does not distinguish between geogenic rock and biogenic reef.

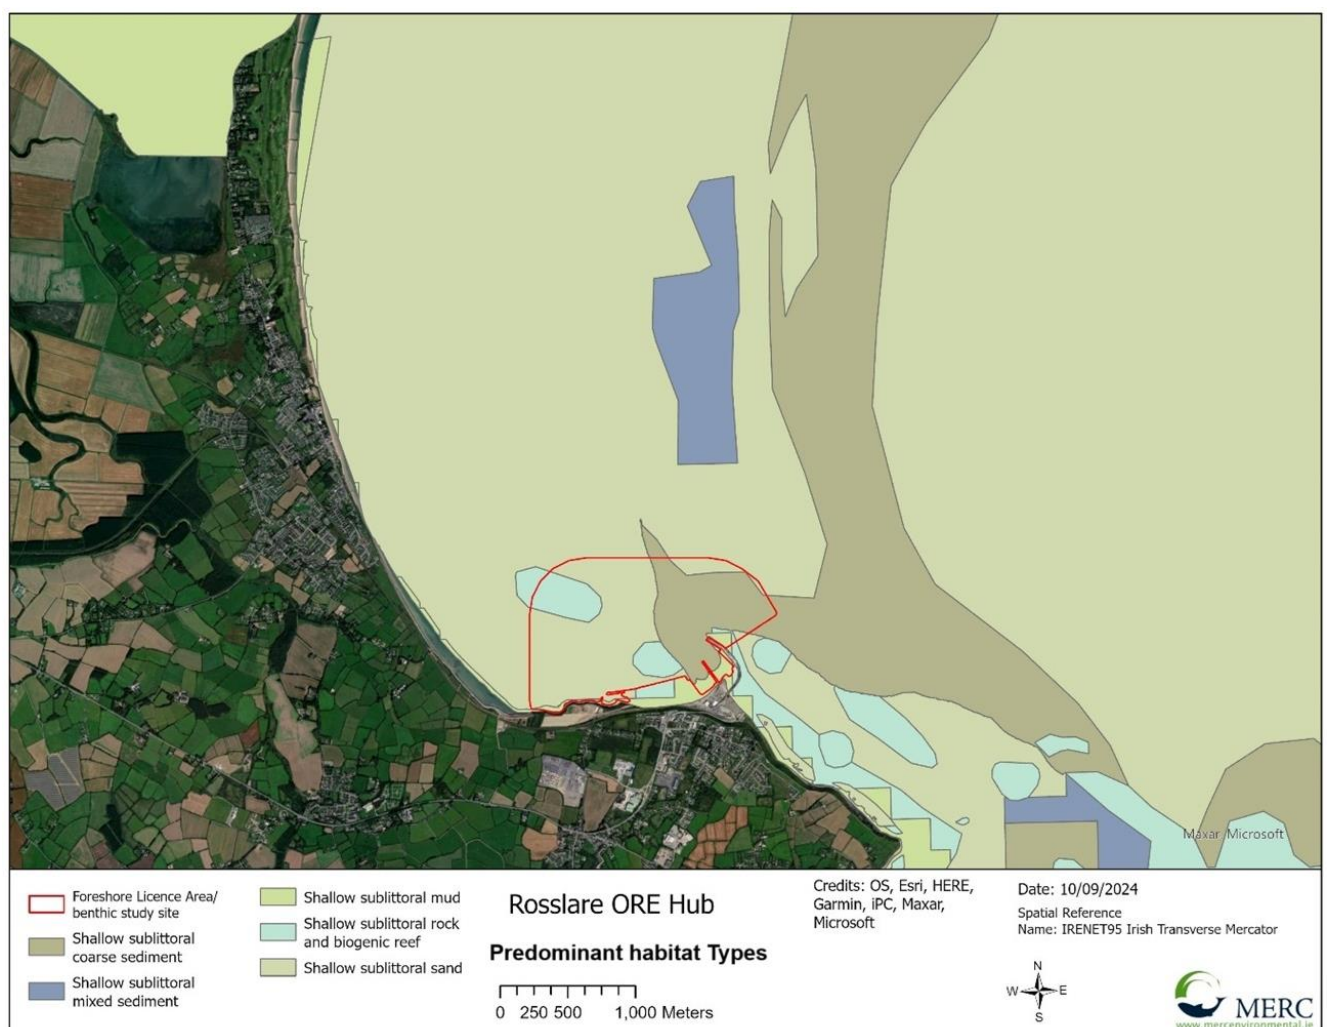

Figure 11-3. Predominant habitat types

Previous benthic surveys within the harbour area (AQUAFAC, 2008) describe the area as being characterised as fine sand to gravel with four biotopes present: *Nephtys hombergii* and *Tubificoides* spp. in variable salinity infralittoral soft mud (SS.SMU.SMuVS.NhomTubi); *Sertularia cupressina* and *Hydrallmania falcate* on tide-swept circalittoral cobbles and pebbles (SS.SSA.IFiSa.ScupHud); *Fabulina fabula* and *Magelona mirabilis* with venerid bivalves and amphipods in infralittoral compacted fine sand (SS.SSA.IMuSa.FfabMag) and Piddocks with a sparse associated fauna in upward-facing circalittoral very soft chalk or clay (CR.MCR.SfR.Pid).

The intertidal area within Ballygeary Harbour (small boat harbour) is described by AQUAFAC (2000) as being characterised by sand, shingle and small stones with a fine coating of mud at the low water mark on which some *Fucus vesiculosus* and *F. serratus* grow. Intertidal fauna within Kilrane Harbour includes *Deshayesorchestia deshayesii* and other talitrid crustaceans in the upper shore, along with the polychaete *Spio filicornis*, talitrids, the bivalve mollusc *Abra alba* and juvenile Mytilidae (mussels) in the mid shore and the polychaetes *Lanice conchilega* and *Kefersteinia cirrata* and the molluscs *Abra alba*, juvenile Mytilacea and *Ruditapes decussatus* in the lower shore. West of Kilrane Harbour the intertidal area comprises a mixture of bedrock, rocks, pebbles and gravel. Intertidal flora here includes the lichens *Verrucaria* and *Xanthoria* in the splash zone, along with *Pelvetia canaliculata*, *Entomorpha*, *Ascophyllum nodosum*, *Fucus spiralis*, *F. vesiculosus*, *Chondrus crispus*, *F. serratus*, *Laminaria digitata* and encrusting red algae from the upper to lower shore. Fauna of this intertidal zone include *Littorina littorea*, *Gibbula umbilicalis*, *Nucella lapillus*, *Patella vulgata*, *M. neritoides*, *Pomatoceros* sp., *Lanice conchilega*, *Littorina fabalis* and barnacles (AQUAFAC, 2000).

11.3.2 SUBTIDAL GRAB SAMPLING

The results of the individual grabs are presented in appendices 1 to 3 as follows:

- Appendix 1: Environmental data sheets
- Appendix 2: Macro faunal data
- Appendix 3: Particle size Analysis (PSA) and Total Organic Carbon (TOC)

The location of each station is shown in Figure 11-4 and the coordinate of each of these locations is given in Appendix 1 (environmental data sheets).

Sediments in the Benthic Study Site were dominated by sands (between 63 µm – 2 mm particle diameter); these size fractions were present in all stations sampled. It was observed that stations split into two broad sediment groups. Stations 1, 2, 5, 14, 31, 34, 36, 37, 38 & 39 were coarse in nature and had a high gravel content, with sediments from these stations comprising of more than 23% of particles >2 mm in diameter. This was coupled with a low silt/clay content of <10% in all cases. They were defined as gravelly sand, sandy gravel or gravel using the Folk Classification system (Table 11-2). Except for station 23, which contained approximately 70% silt/clay particles and was defined as sandy mud, all other stations were dominated by sands of very fine and fine size fractions (63 µm – 249 µm) and classified as muddy sand or sand under the simplified Folk Classification system.

Total organic carbon ranged from 0.86% at station 8 to 7.39% at station 23, which showed that no stations suffered from organic enrichment whether of natural or anthropogenic sources. Levels of TOC

correlated well with proportion of silt/clay particles (Figure 11-5). Some of the gravel stations with <10% silt/clay particles had slightly higher levels of TOC, but these were well within 'normal' ranges.

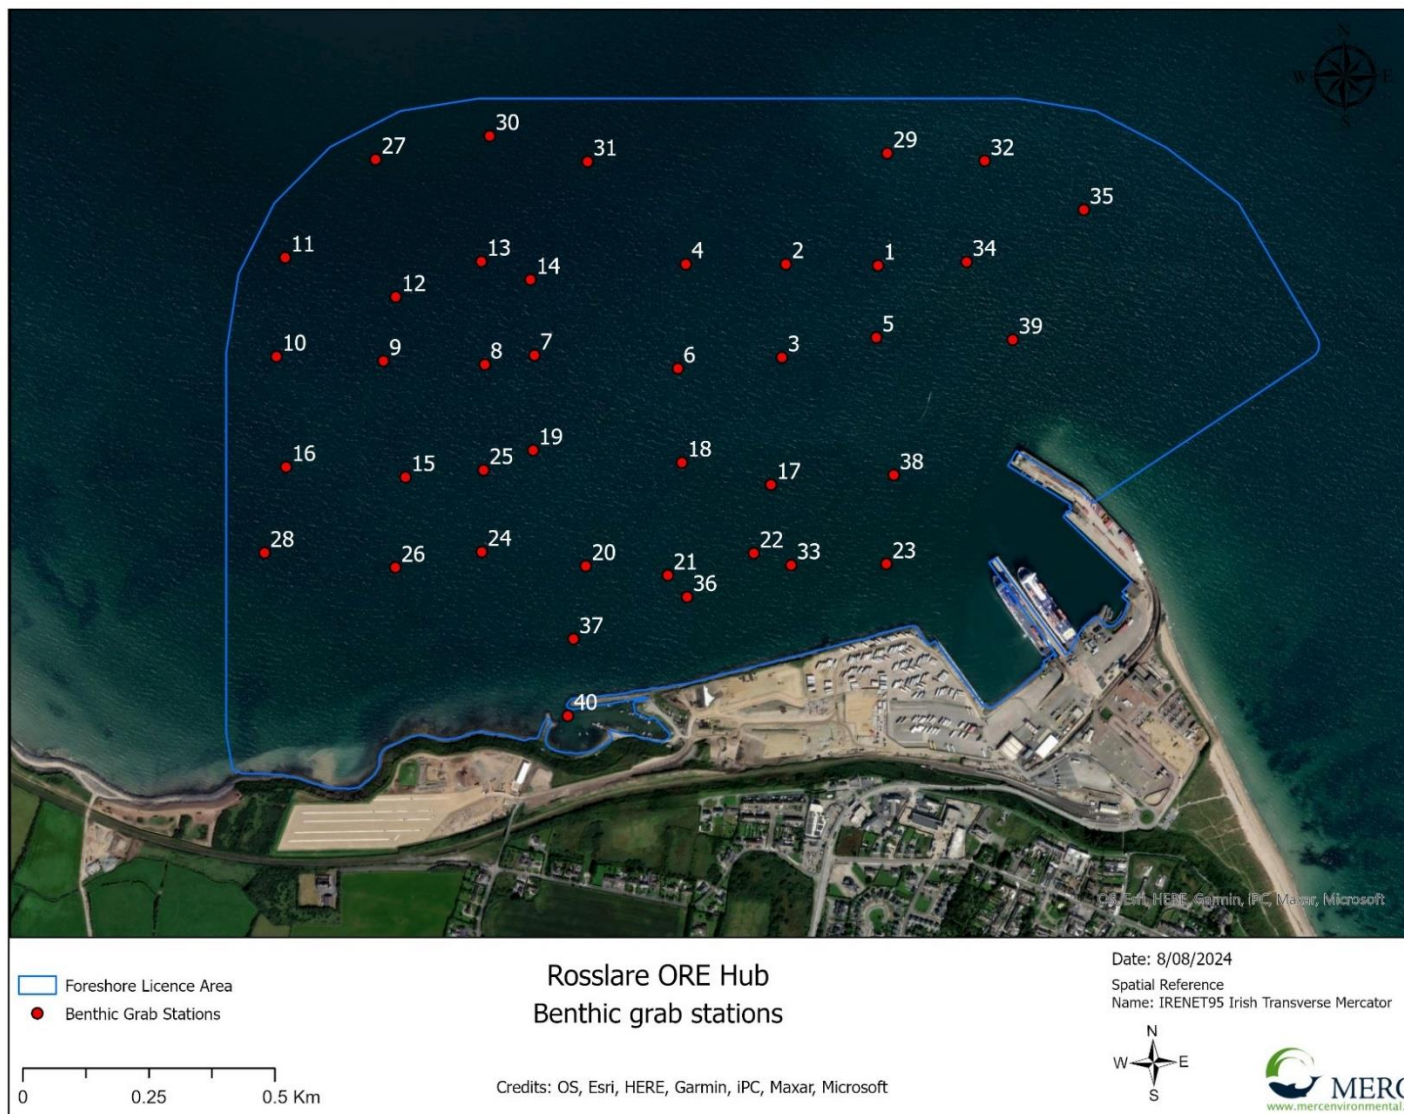

Figure 11-4. Benthic grab stations

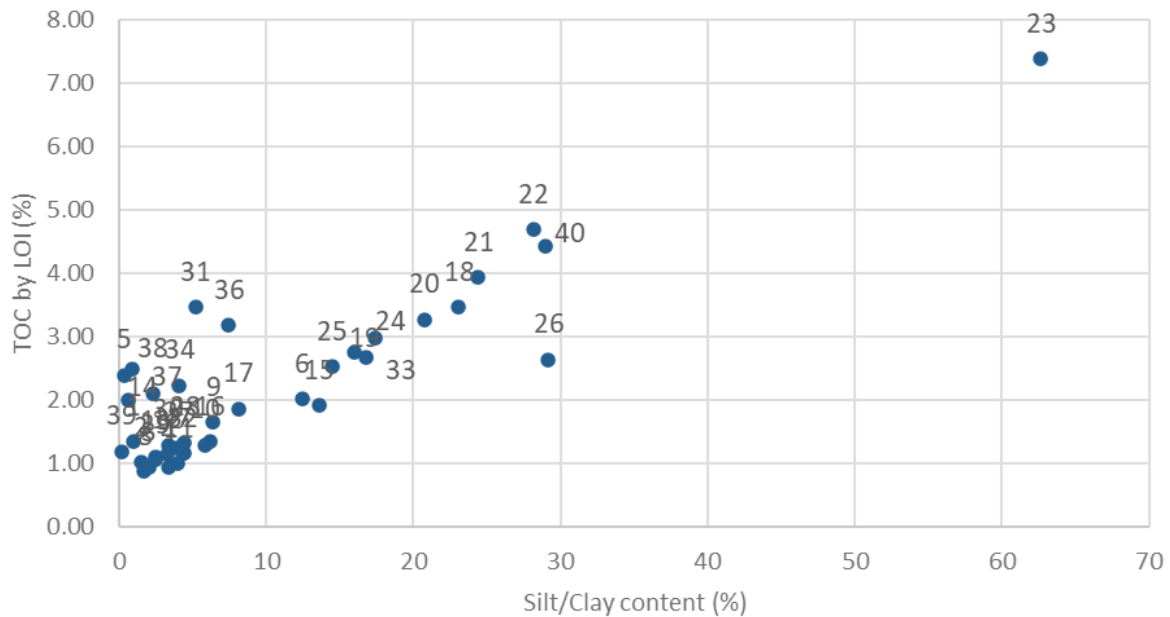

Figure 11-5. Silt/clay content vs. Total organic carbon at each station surveyed in the Rosslare Europort ORE Hub Benthic Study Site in 2024

The number of species sampled ranged from 19 taxa per 0.1 m² at station 39 to 77 taxa per 0.1 m² at station 2 and the average for the whole of the survey area was 40 taxa per 0.1 m². Abundance was extremely high at some stations, where the bivalve *Abra alba* heavily dominated the community. For example, at station 18, an average of 1,911 individuals were recorded per 0.1 m². This was compared to a median abundance value across the survey area of 164.5 individuals per 0.1 m². At many stations evenness and diversity were low, for example at station 17, Shannon-Weiner diversity was 1.0 and Pielou's evenness 0.26; this was due to the numerical dominance of a few taxa. The highest diversity of 3.36 was recorded at station 2 where abundance was spread relatively evenly across all taxa recorded (Table 11-3).

Table 11-3. The diversity indices S (number of species), N (abundance), J' (Pielou's evenness) and Hlog_e (Shannon-Weiner diversity) at each station surveyed in the Rosslare Europort ORE Hub Benthic Study Site in 2024

39	19	12.67	0.86	2.49
40	39	243.33	0.46	1.54

Cluster analysis using Bray-Curtis similarity values showed that statistically significant differences occurred between many groups of stations (Figure 11-6). At a similarity level of approximately 15%, one group of stations – 1, 5, 34, 38, 39 & 40 – was found to be significantly different to all other stations, and then another cluster of stations – 2, 31, 35, 36 & 37 – separated at approximately 30% similarity. Except for station 4, which was a slight outlier, all other stations had a similarity of 45% or more. The nMDS (Figure 11-7) showed that the majority of groups were placed close together on the left side of the plot, whilst the stations with a low similarity to this group were scattered on the right side of the plot.

A shade plot was used to examine the specific taxa which numerically dominated at stations in the Benthic Study Site (Figure 11-8). The high abundances of the bivalve mollusc *Abra alba* can clearly be seen across almost the whole survey area. The communities at the majority of stations also contained high or moderate numbers of the polychaetes *Nephtys hombergii* and *Euclymene oerstedii* and the bivalve *Nucula nitidosa*. Also commonly recorded but not in high abundances were the polychaetes *Notomastus*, *Glycera tridactyla*, *Ampharete lindstroemi* and *Galathowenia oculata*.

At stations 1, 2, 4, 5, 31, 34, 35, 36, 37, 38, 39 & 40, communities contained lower abundances of animals described above and also were comprised of epifaunal taxa such as anemones (*Actiniaria*) and the keel-worm *Spirobranchus lamarcki*. The oligochaete *Tubificoides benedii* and polychaete *Cirriformia tentaculata* both typical of estuarine waters, were also common at these stations.

The communities at stations 23, 33 & 40 comprised the polychaetes *Capitella* and *Malacoceros vulgaris* which are both indicative of organic enrichment (either natural or anthropogenic). However, abundances across replicates were very variable at stations 23 and 33, whilst at station 40 both taxa were recorded at moderate abundance (50-165 individuals per 0.1 m²) in all replicates. Although stations 23 had the highest total organic carbon content in the survey area, it also had the highest silt/clay content, and the levels were not high enough to indicate organic enrichment.

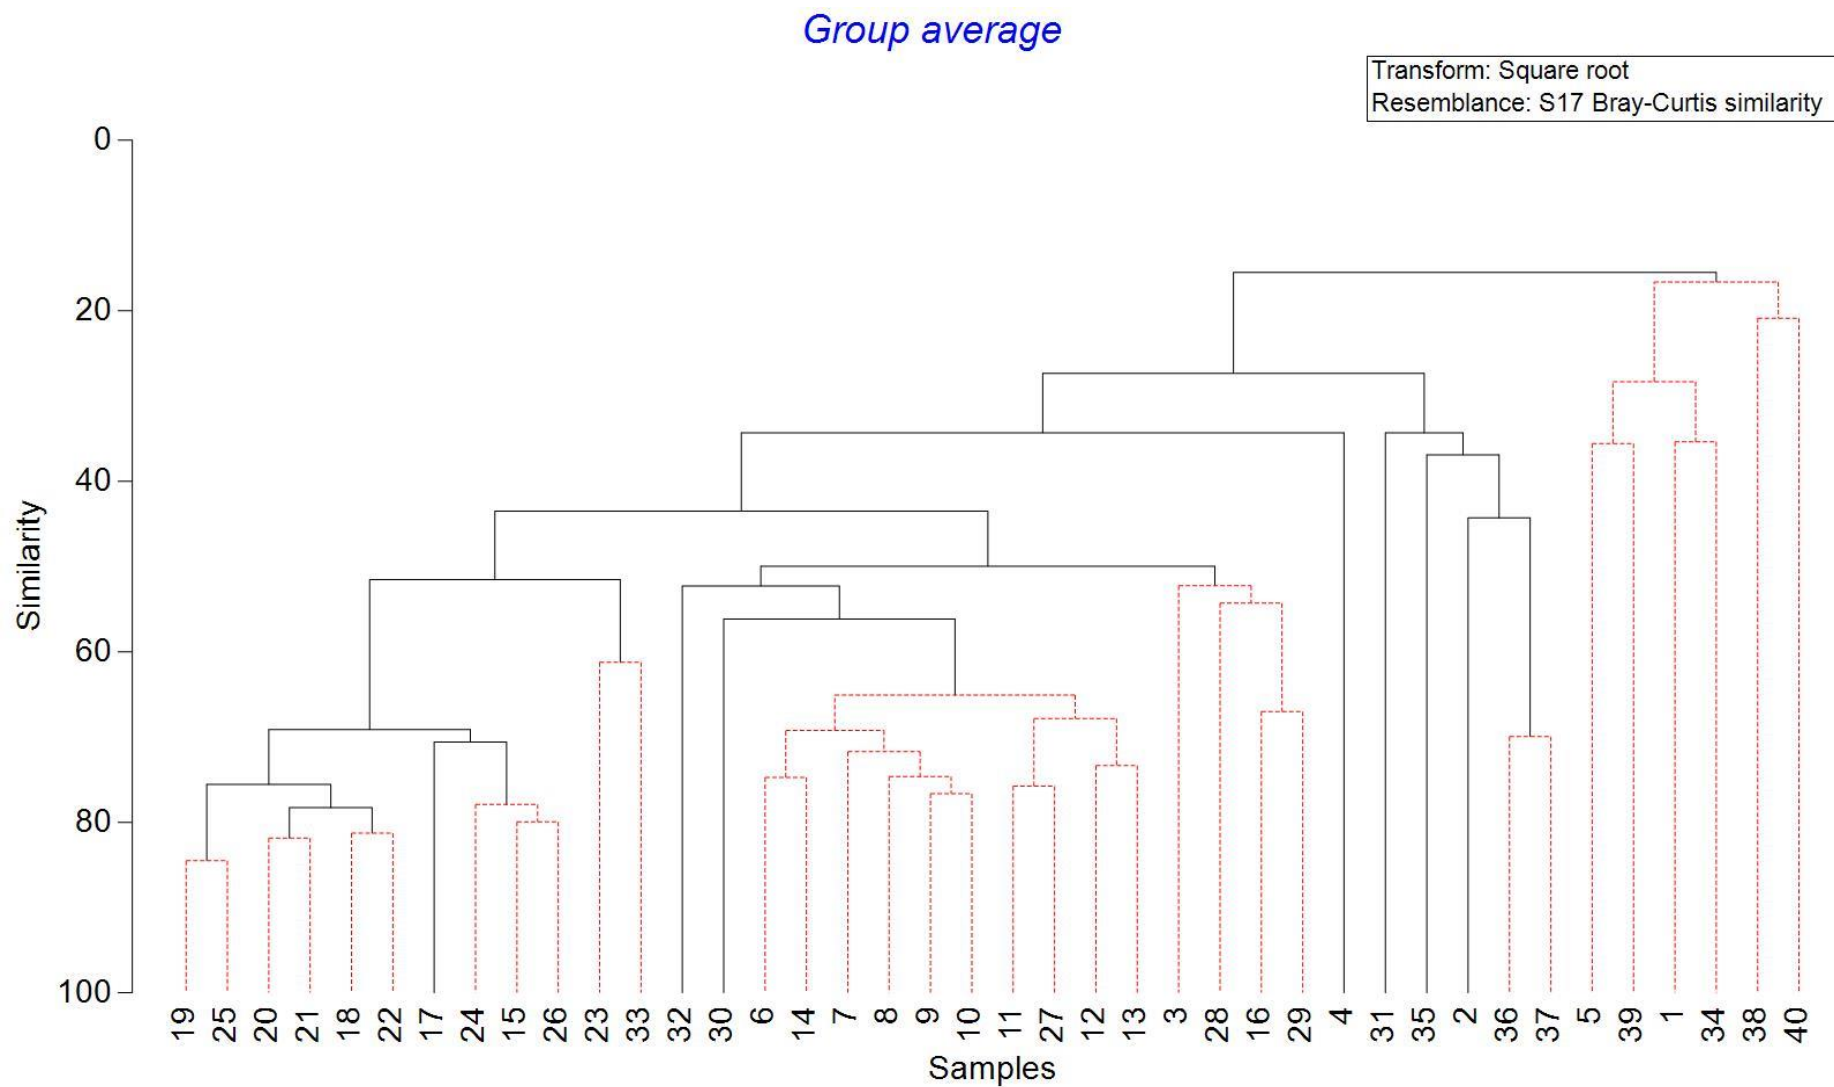

Figure 11-6. Dendrogram of the cluster analysis of Bray-Curtis similarity scores on the square-root transformed station averaged data

Non-metric MDS

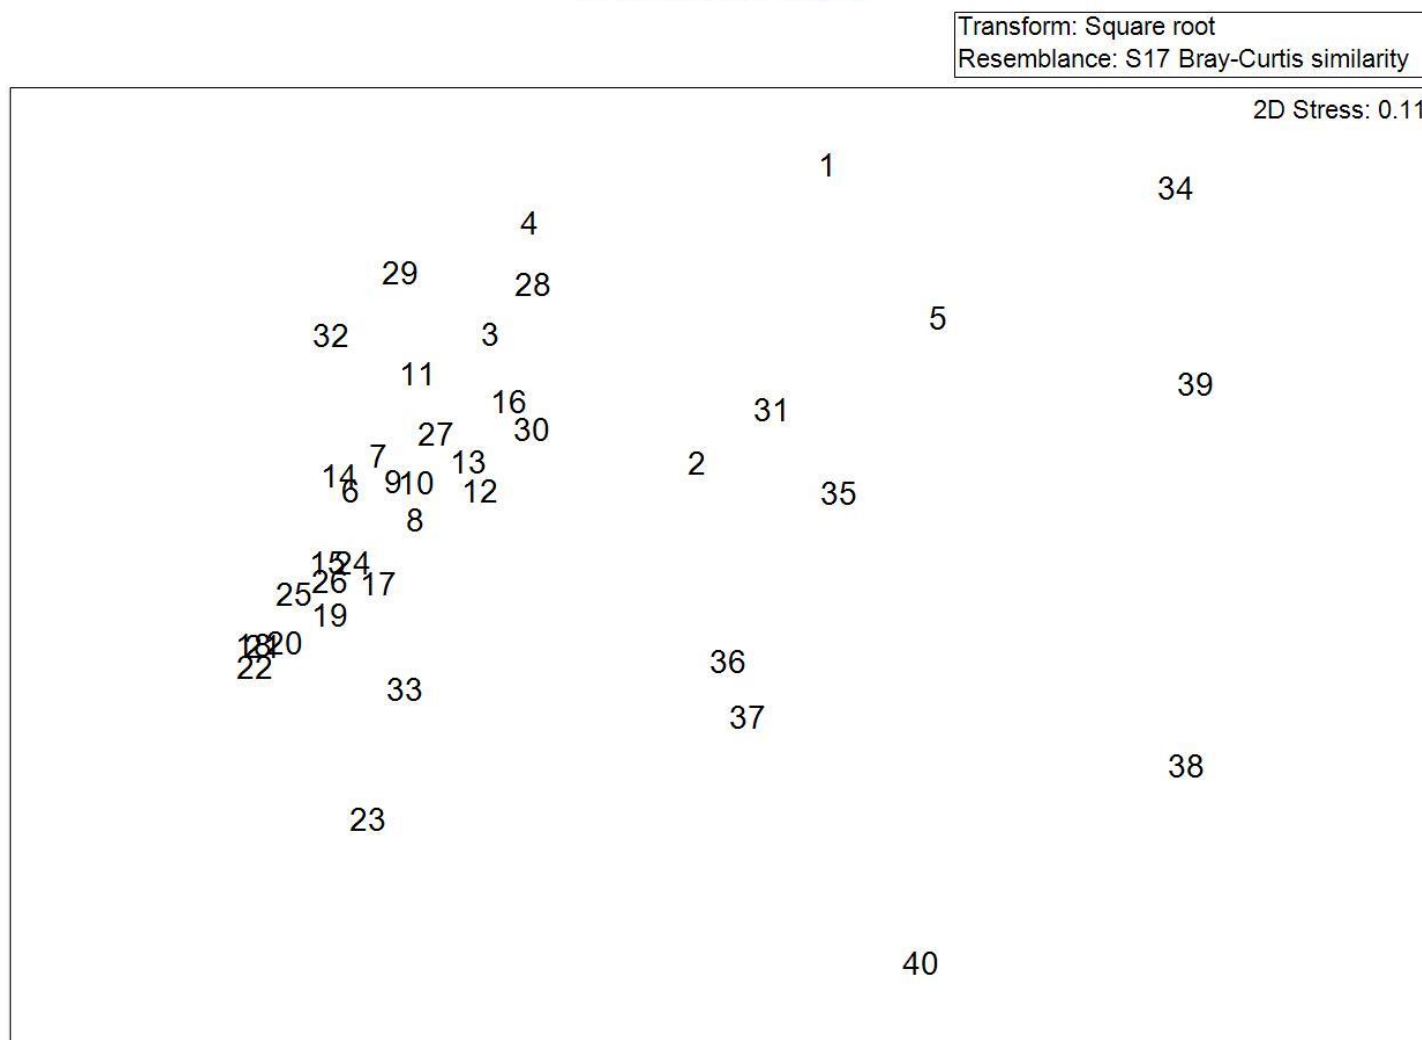

Figure 11-7. nMDS ordination plot of square-root transformed Bray-Curtis similarity abundance data (station averaged)

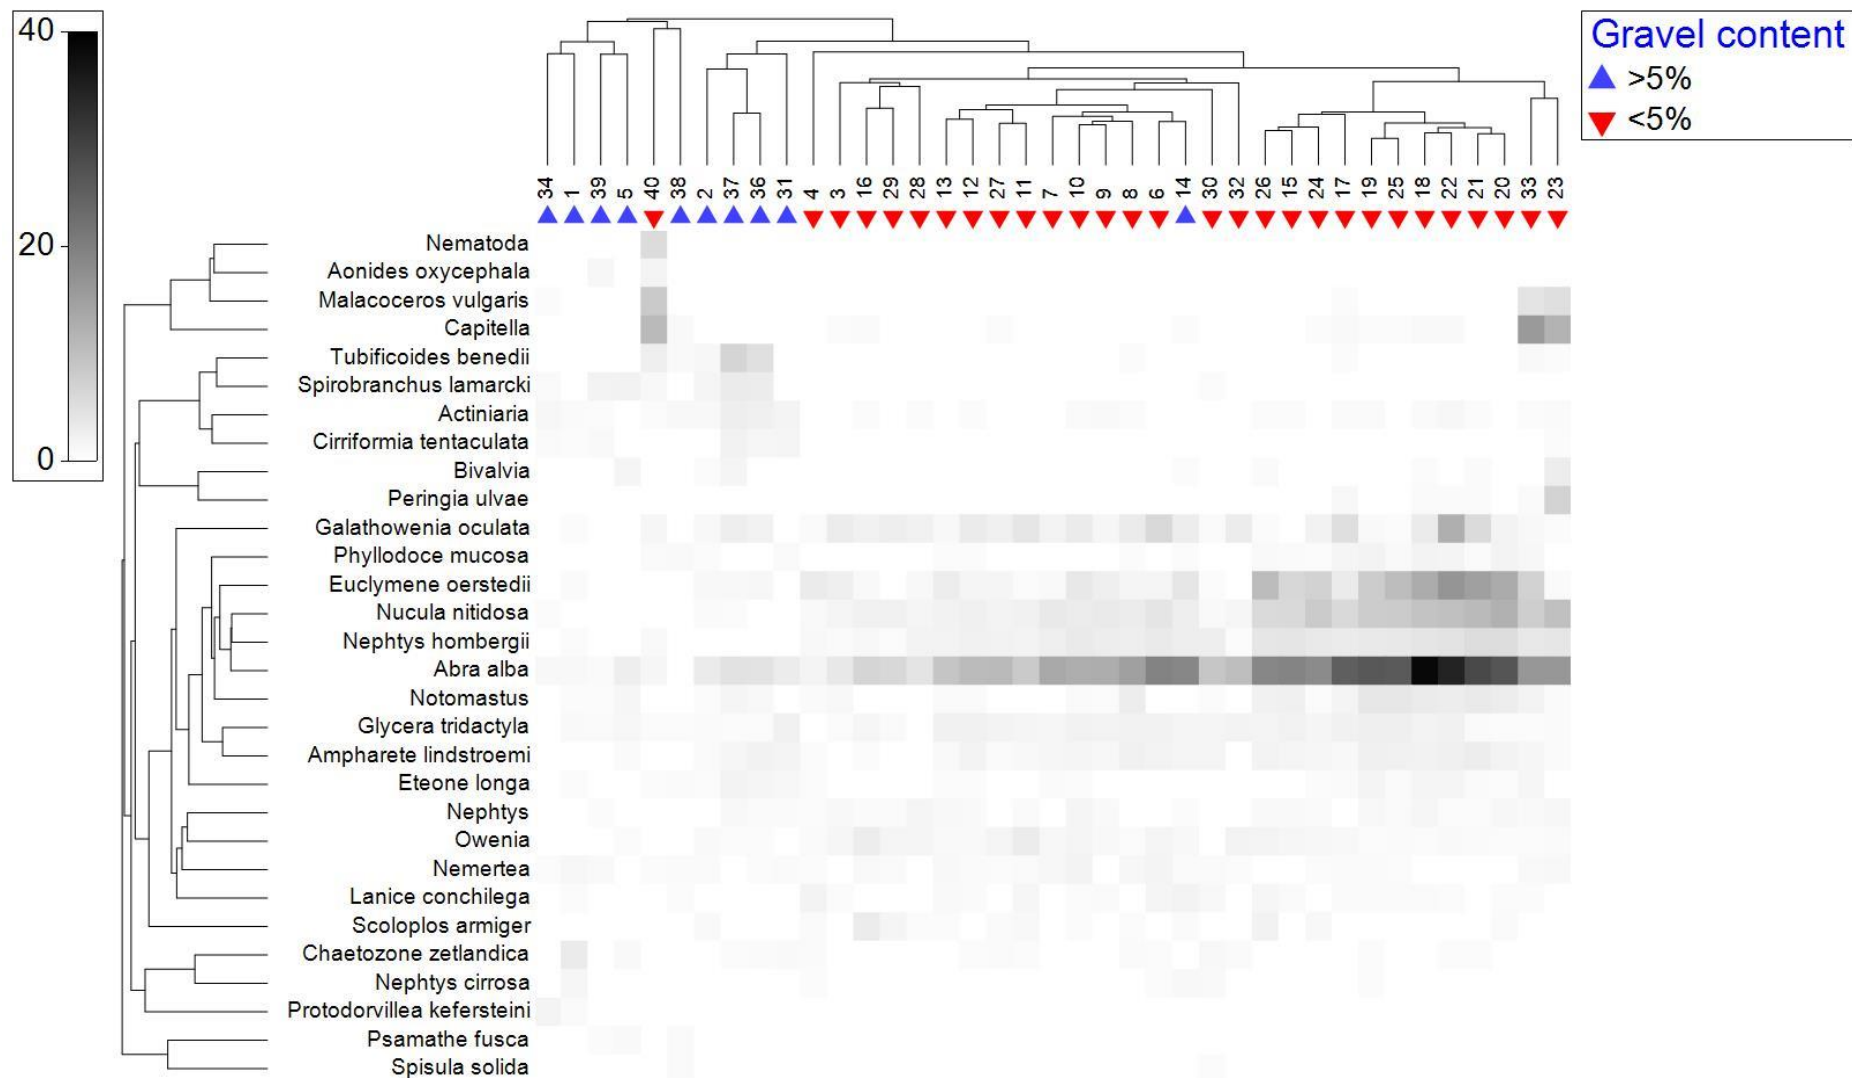

Figure 11-8. Shade plot of the square-root transformed per station abundance data. Symbols showed where stations contained more than 5% gravel and less than 5% gravel content

The biological data were linked with the environmental data (PSA and TOC) using the “BEST” tool in Primer to examine which variables best explained the observed differences between the communities. The combination of variables which correlated best with the biological data ($r = 0.723$) were small pebble (4-8 mm), granule (2-4 mm), sand- very coarse (1-2 mm) and total organic carbon. Other combinations were also closely correlated ($r =$ between 0.710-0.721) and also included medium pebble and upwards (8 mm+) and silt/clay ($<63 \mu\text{m}$). Sediment in the gravel fractions proved to be important in explaining variance and so were plotted as symbols on a shade plot (Figure 11-8). Figure 8 shows that stations with high number of *Abra alba*, *Nephtys hombergii*, *Eucliyemen oerstedii* and *Nucula nitidosa* were those comprised of smaller proportions of gravel and finer sediments.

Biotopes were assigned to each station based on the sediment and biological data (Table 11-4). Many of the coarser ‘gravel’ stations contained difficult to define biotopes, possibly because these were the stations subjected to sporadic high currents due to maneuvering of ships, which may have led to the creation of an ‘artificial’ habitat, i.e. not one which would be positioned there in less disturbed conditions.

Table 11-4. Station biotopes

No.	Biotope code	Biotope	Notes

11.3.3 SUBTIDAL DROPDOWN VIDEO SURVEY

Informed by the multibeam data and benthic grab sampling survey, a series of video drops were conducted throughout the Benthic Study Site and included areas of soft sediment and potential reef habitat.

The locations of each dropdown video transect are shown in Figure 11-9. Video transects over or adjacent to the grab sampling stations showed a relatively level sediment seabed, with frequent areas of *Lanice conchilega* or its associated tube debris on the surface. An area of rippled sand was also present, likely associated with the vessel manoeuvring area, a feature also evident from the multibeam data. A full description of the macrobenthic communities present in the sediment areas is given in Section 11.3.2. Areas of cobble reef are present within the site. These can be clearly seen from the multibeam data used to inform the locations of video drops, to ensure sufficient sampling was conducted to characterise these areas. Table 11-5 describes the habitat at each video transect.

All reef habitat recorded was characterised by the biotope IR.HIR.KSed.ProtAhn: *Polyides rotundus*, *Ahnfeltia plicata* and *Chondrus crispus* on sand-covered infralittoral rock. Example images of this biotope taken from the video imagery are shown in Figure 11-10 and Figure 11-11.

This biotope was present on cobble within the depth range of 3.2-7.3 meters. The video log (Appendix 6) generally records this reef biotope as being in mosaic with sediment biotopes, including mixed sediments (Figure 11-12 and Figure 11-13) as the entire transect was rarely comprised of reef alone. Where present, it was generally covered by a veneer of sand and was found to support species tolerant of sand scour.

Ahnfeltia plicata, *Polyoides rotundus* and *Calliblepharis ciliata* were present at the majority of the video drops on cobble. *Halidrys siliquosa*, *Callophyllis laciniata* and *Fucellaria lumbricalis* were also frequently recorded. Faunal biomass and diversity were poor, as is typical for this biotope. *Anemonia viridis* and *Cereus pedunculatus* were the most frequently recorded faunal species.

Aggregations of the common spider crab (*Maja brachydactyla*) was a feature of the cobble reef biotopes within the survey area (Figure 11-14). This species was also recorded on soft sediments, but aggregated at reef habitats and was also found to be associated with discarded fishing gear.

A biotope map, showing the distribution of the reef biotopes within the survey area, prepared through interpolation of the results of the dropdown video survey analysis and multibeam data, is shown in Figure 11-15. Where data was absent for the shallow sublittoral southwest section of the site, the overarching Habitat Complex was applied (e.g. Sublittoral sands and muddy sands).

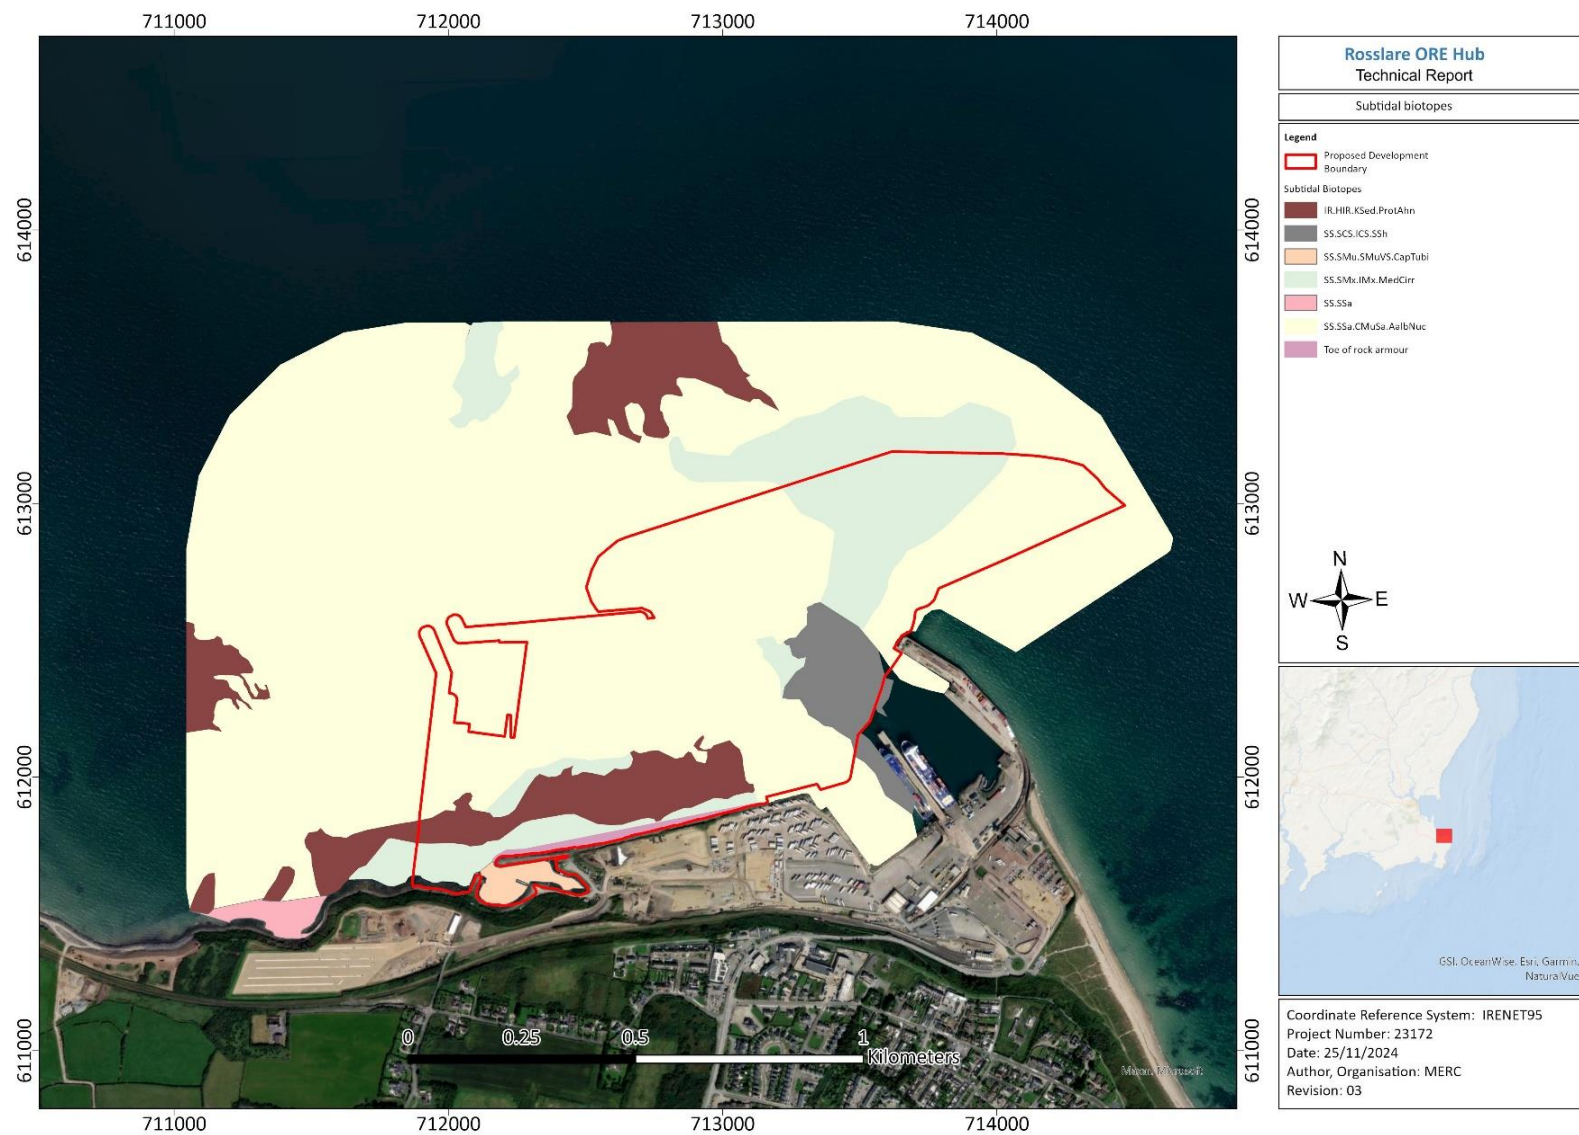

Figure 11-15. Subtidal biotope map

11.3.4 INTERTIDAL ECOLOGY

The Small Boat Harbour (Ballygeary Harbour) lies within a small, enclosed bay protected from the east by rock armour. Here, the intertidal area is dominated by cobble and small boulders. It lacks significant physical features such as rockpools, crevices or overhangs that can add diversity to the habitat. The inner section of the harbour, east of the main slip and pontoon, is sheltered and dominated by fucoids with areas of *Ascophyllum nodosum* present. The brown algae, *Fucus ceranoides*, was abundant in the most easterly section of the inner harbour, indicating low salinity. This species is generally associated with freshwater input. However, there is no obvious source of freshwater (streams) entering the harbour.

The area has been heavily impacted by the presence of the rock armour and ancillary facilities for access to small boats. Litter and fishing debris is frequent throughout the area.

West of the spit, the area is more exposed, and the intertidal area is characterised by a mosaic of habitats including areas of mixed sediment, sand and cobble and boulder reef. Anthropogenic impacts are less in the more exposed outer section of the site.

Four intertidal biotopes are present within the intertidal area of the Benthic Study Site:

- *Fucus vesiculosus* on moderately exposed to sheltered mid eulittoral rock (LR.LLR.F.Fves).
- *Fucus ceranoides* on reduced salinity eulittoral rock (LR.LLR.FVS.Fcer)
- *Fucus spiralis* on exposed to moderately exposed upper eulittoral rock (LR.MLR.BF.FspiB)
- *Fucus serratus* on moderately exposed lower eulittoral rock (LR.MLR.BF.Fser)

Within the small boat harbour, LR.LLR.FVS.Fcer is generally confined to the most easterly section of the area, while the remainder of the site is characterised by LR.LLR.F.Fves. The outer section of the site, west of the spit, is more exposed and, depending on the shore height, characterised by a mosaic of the biotopes LR.MLR.BF.FspiB and LR.MLR.BF.Fser. As is common with all of these biotopes, species diversity was low, and no rare or unusual species were recorded.

A list of the species recorded at the site and their abundance is given in Table 11-6 and

Table 11-7 and a biotope map for the area is presented in

Figure 11-16. Intertidal biotopes

11.3.5 WATER SAMPLING

The sample station locations, together with the field sampling data, are given in Table 11-8. Station locations are shown in Figure 11-17. The results of the laboratory analysis are given in Table 11-9. The results indicated that all samples were just below full salinity, ranging from 32.9 to 33.6 parts per thousand (PPT). There were no significant differences in any of the parameters measured across the 15 stations.

Table 11-8. *In-situ* water sampling data

11.4 CONCLUSIONS

The subtidal area within the Benthic Study Site is dominated by a sediment biotope with characteristics of the biotope *Mediomastus fragilis* and cirratulids in infralittoral mixed sediment (SS.SMx.IMx.MedCirr) with smaller areas of the sediment biotope *Abra alba* and *Nucula nitidosa* in circalittoral muddy sand or slightly mixed sediment (SS.SSa.CMuSa.AalbNuc) towards the east of the site. Cobble reef corresponding to the biotope *Polyides rotundus*, *Ahnfeltia plicata* and *Chondrus crispus* on sand-covered infralittoral rock (IR. HIR.KSed.ProtAhn) is present in areas adjacent to the southern shore and also on the northern and western perimeters. Areas corresponding to the biotope Sparse fauna on highly mobile sublittoral shingle (cobbles and pebbles) (SS.SCS.ICS.SSh) are present to the east of the site close to the existing quays.

The biotope *Mediomastus fragilis* and cirratulids in infralittoral mixed sediment, which was assigned to a large proportion of the study site, is considered to be a very loose match. However, it is well recognised that many of the Marine Nature Conservation Review (MNCR) biotopes are difficult to assign to Irish habitats due to the limited Irish data included within the Marine Habitat Classification of Britain and Ireland (Connor *et al*, 2004). For this reason, National Parks and Wildlife Service (NPWS) uses a system of Marine Community Complexes to assess areas which have similar abiotic features but records a number of biological communities that are not regarded as being sufficiently stable and/or distinct temporally or spatially to become the focus of conservation efforts.

According to the Marine Habitat Classification of Britain and Ireland (Connor *et al*, 2004), the biotope SS.SMx.IMx.MedCirr is found on infralittoral shallow mixed sediment, characterised by diverse number of cirratulid polychaetes, bivalves and amphipods. This biotope has been recorded in Bembridge, located in the Eastern English Channel on the east of the Isle of Wight.

The biotope IR.HIR.KSed.ProtAhn, as with all reef biotopes, corresponds to the EU Annex I habitat Reefs (Habitat code 1170). It is found on low-lying rock surrounded by mobile sand and often subject to burying by the sand, with a turf of resilient red seaweeds *Chondrus crispus*, *Polyides rotunda* and *Ahnfeltia plicata* typically protruding through the sand on the upper surfaces of the rock. Other scour-tolerant seaweeds typically cover the rock, while scattered individuals of the brown seaweeds *Halidrys siliquosa*, *Cladostephus spongiosus*, *Dictyota dichotoma* and *Saccharina latissima* can be present. The large anthozoan *Urticina felina* can occur in this biotope but there are few other conspicuous animals (Connor *et al*, 2004).

The intertidal area within the study site is characterised by cobble and small boulders dominated by fucoids. Four separate fucoid biotopes were recorded, all of which are common in Ireland and representative of a relatively sheltered intertidal location. The area is heavily impacted due to the creation of boulder defences and the creation of makeshift jetties.

No rare or unusual species were found in either the intertidal or subtidal areas sampled. No obvious Invasive Alien Species (IAS) were recorded on any of the surveys conducted. However, specific surveys for IAS along jetties and quay walls were not carried out.
